The Fast Guide to Cartesian Coordinate Planes

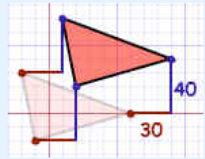

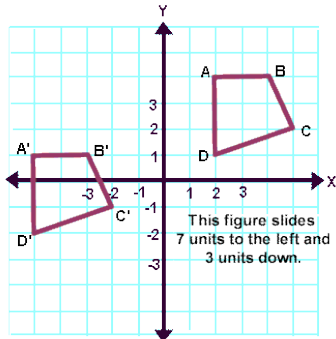

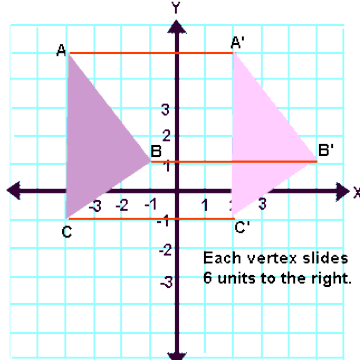

Transformations:

The word transform means "to change." In geometry, a transformation changes the position of a shape on a coordinate plane. What that really means is that a shape is moving from one place to another. There are three basic transformations:

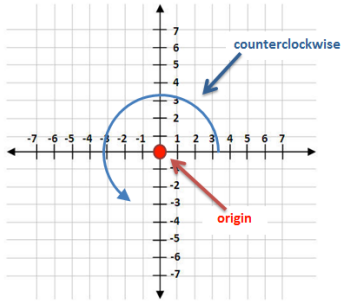

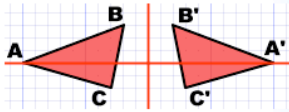

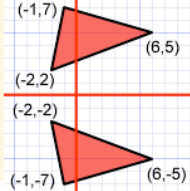

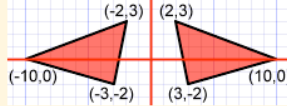

- Flip (Reflection)
- Slide (Translation)
- Turn (Rotation)

The **figure** is the original shape or set of points, the **image** is the new shape or set of points.

Transformation	Explanation
Translation (Slide)	<p>Translations take place when a shape moves in one direction from one place to another in a straight line. The figure and the image have the same size and shape. You can describe a translation as up or down or right and left.</p> <p>Example: when we want to say the shape gets moved 30 Units in the "X" direction, and 40 Units in the "Y" direction, we can write:</p> $(x, y) \rightarrow (x + 30, y + 40)$ <p>Which says "all the x and y coordinates will become x+30 and y+40"</p> <div style="display: flex; justify-content: space-around; align-items: flex-end;">  </div> <div style="display: flex; justify-content: space-around; align-items: flex-end;">   </div>

Transformation	Explanation						
Rotation (Turn)	<p>Rotations are when a shape turns on a point away from its original position. It almost looks like a clock hand turning around the face of a clock. The distance from the center to any point on the shape stays the same. Every point makes a circle around the center.</p> <p>Shapes can rotate by four different angles. When it rotates by 90°, it looks like it is laying on its side. When it rotates by 180°, it looks like it is upside down. When it rotates by 270°, it also looks like it is lying on its side. A 360° rotation means the shape will turn all the around.</p> <p>A positive angle of rotation turns the figure counterclockwise, and a negative angle of rotation turns the figure in a clockwise direction.</p>  <table border="1" data-bbox="462 871 1409 1012"> <tbody> <tr> <td>Rotation of 90°:</td><td>$R_{90^\circ}(x, y) = (-y, x)$</td></tr> <tr> <td>Rotation of 180°:</td><td>$R_{180^\circ}(x, y) = (-x, -y)$ (same as point reflection in origin)</td></tr> <tr> <td>Rotation of 270°:</td><td>$R_{270^\circ}(x, y) = (y, -x)$</td></tr> </tbody> </table>	Rotation of 90° :	$R_{90^\circ}(x, y) = (-y, x)$	Rotation of 180° :	$R_{180^\circ}(x, y) = (-x, -y)$ (same as point reflection in origin)	Rotation of 270° :	$R_{270^\circ}(x, y) = (y, -x)$
Rotation of 90° :	$R_{90^\circ}(x, y) = (-y, x)$						
Rotation of 180° :	$R_{180^\circ}(x, y) = (-x, -y)$ (same as point reflection in origin)						
Rotation of 270° :	$R_{270^\circ}(x, y) = (y, -x)$						
Reflection (Flip)	<p>A reflection takes place when a shape is flipped across a line and faces the opposite direction. Because the shape ends up facing the opposite direction, it appears to be reflected, as in a mirror. A shape can reflect across the y-axis, the x-axis, or across a bisector (diagonal line).</p> <p>Labels</p> <p>It is common to label each corner with letters, and to use a little dash (called a Prime) to mark each corner of the reflected image.</p>  <p>Here the original is ABC and the reflected image is A'B'C'</p> <p>Some Tricks</p> <div data-bbox="519 1533 1047 1743"> <p>X-Axis</p> <p>When the mirror line is the x-axis we change each (x,y) into (x, -y)</p>  </div> <div data-bbox="519 1764 1347 1879"> <p>Y-Axis</p> <p>When the mirror line is the y-axis we change each (x,y) into (-x, y)</p>  </div>

Rotations

Rotation notation is usually denoted $R_{(\text{center}, \text{degrees})}$

- "Center" is the 'center of rotation.' This is the point around which you are performing your mathematical rotation (this can be on the figure or off the figure)
- "Degrees" stands for how many degrees you should rotate. Positive rotations are **counterclockwise** and negative rotations are **clockwise**.

Rotation	If I started in quadrant I I'll end up in...
90°	Quadrant II (negative x-axis)
180°	Quadrant III (negative y-axis)
270°	Quadrant IV (positive x-axis)
306°	Quadrant I (positive y-axis)

Rotation by 90° about the origin

$R_{(\text{origin}, 90^\circ)}$: A rotation by 90° about the origin can be seen in the picture below in which A is rotated to its image A'.

The general rule for a rotation by 90° about the origin is:
 $(A, B) \rightarrow (-B, A)$

Example:

$(-1, 2) \rightarrow (2, 1)$

Rotation by 180° about the origin

$R_{(\text{origin}, 180^\circ)}$: A rotation by 180° about the origin can be seen in the picture below in which A is rotated to its image A'.

The general rule for a rotation by 180° about the origin is:
 $(A, B) \rightarrow (-A, -B)$

Example:

$(-2, -1) \rightarrow (2, 1)$

Rotation by 270° about the origin

$R_{(\text{origin}, 270^\circ)}$: A rotation by 270° about the origin can be seen in the picture below in which A is rotated to its image A'.

The general rule for a rotation by 270° about the origin is:
 $(A, B) \rightarrow (B, -A)$

Example:

$(2, 1) \rightarrow (1, -2)$
